Sets: The basics

Sets are the fundamental building block of modern mathematics. Intuitively, a set is a collection of objects, but with two important twists:

- 1. Sets are unordered.
- 2. Sets contain no duplicates.

EXAMPLE 1.

Sets: The basics

Suppose you want to keep a record of which words occur in a text. You aren't interested in how often a given word occurred, just whether it occurs at all. Nor do you care in which order the words occurred in the text. So you are actually interested in the *set* of words that occur in the text.

Each property is explained in detail below, but let's first put some helpful notation in place.

1 List notation

Sets are often written as lists with curly braces around them. So $\{a, b, c, d\}$ denotes the set containing a, b, c, d. Here a, b, c, d are some arbitrary objects. This is known as **list notation**. More complex sets are defined with **set-builder notation**, which will be covered in a later unit.

EXAMPLE 2.

Consider the string *If John slept, then Mary left*. Its set of words (ignoring sentence-initial capitalization) is {if, John, left, Mary, slept, then}.

Exercise 1.

Write the following as a set:

- the first names of your three favorite actors/actresses,
- the colors of the rainbow,
- all prime numbers between 1 and 10 (remember, 1 is not a prime number!)

2 Elements and set membership

The objects contained in a set are called its **elements** or **members**. One writes $e \in S$ to indicate that e is an element of S. The opposite is denoted $e \notin S$: e is not an element of S. The symbol \in thus indicates **set membership**.

Sets: The basics

EXAMPLE 3.

Let W be the set of words in the string If John slept, then Mary left. Then it holds that $left \in W$ and $right \notin W$. But it is not the case that $then \notin W$ or $awake \in W$.

Sometimes \ni is used as the mirror image of \in . For example, $a \in S$ could also be written as $S \ni a$.

Example 4.

Continuing the previous example, it is true that $left \in W \ni then$. That is to say, both $left \in W$ and $then \in W$ are true.

Exercise 2.

Put \in , \ni , \notin , $\not\equiv$ in the gaps below as appropriate:

- 5 {1, 2, 4, 5, 8}
- 6_{1,2,4,5,8}
- {5}_{1,2,4,5,8}
- 5 {1, 2, 4, 5, 8} 6

3 Lack of order

Even though we may write sets in a linear fashion as lists, they have no internal order. The set $\{a,b\}$ could also be written as $\{b,a\}$. So we have $\{a,b\} = \{b,a\}$, and $\{a,b,c\} = \{a,c,b\} = \{b,a,c\} = \{b,c,a\} = \{c,a,b\} = \{c,b,a\}$.

Example 5.

Consider the strings *If John slept, then Mary left* and *If Mary left, then John slept*. While they are clearly distinct sentences, their sets of words are identical.

Exercise 3.

For each one of the following, fill the gap with = or \neq as appropriate:

- $\{a,b\}$ $\{a,b\}$
- $\{b, a\}$ $\{a, b\}$
- $\{b, a, c, d\}$ $\{e, a, b, d\}$

4 Lack of duplicates/Idempotency

Sets are **idempotent**, which means that duplicates are ignored. So $\{a, b\} = \{a, a, b\} = \{a, b, b, a, b, a, b, a, a\}$. It also holds that $\{a\} = \{a, a\} = \{a, a, a\}$, and so on.

Sets: The basics 5 Recap

Example 6.

Linguists distinguish between **word types** and **word tokens**. The sentence *dogs love dogs* contain two tokens of the type *dogs*, and one token of the type *love*. The sentences *dogs love* and *dogs love dogs* are different with respect to word tokens, but identical with respect to word types. So if you care about word types rather than word tokens, you're dealing with a set because the only thing that matters is which words the text contains, not how many tokens of each word.

Example 7.

Consider the sentence *If police police police, then police police police*. Its set of words (ignoring capitalization) is {if, police, then}.

Exercise 4.

For each one of the following, fill the gap with = or \neq as appropriate:

- $\{a,b\}$ $\{a,a,b,b\}$
- $\{b,a\}_{a,b,a}$
- $\{c, b, a, a, d, c\}$ $\{a, a, b, d, c, c, c\}$
- $\{a\}_{\{a,a,a,a,a,a,c,a,a,a,a,a,a,a\}}$

Exercise 5.

The sentence *If police police police, then police police police* actually uses two different word types. It just just so happens that both are pronounced and spelled *police*. But one is the noun *police*, the other one the verb *police*. So we might want to annotate the string as follows: *If police[N] police[N] police[N], then police[N] police[N] police[N]*. Assume that words are annotated with their part of speech in this fashion. Then what would be the corresponding set of words?

5 Recap

- Sets are collections of arbitrary objects.
- Sets are unordered and idempotent (= duplicates are ignored).
- Sets can be defined with list notation, e.g. $\{a, b\}$.
- The objects contained in a set are called its *elements* or *members*.
- The symbols ∈ and ∉ are used to indicate membership and non-membership, respectively.
- Occasionally, \ni is used as the mirror image of \in .
